1 Introduction

This project predicts the valuation price of the danish housing market. By scraping boliga.dk we obtain a broad range of variables of potential interest, on all listed housing by august 23th, 2019. The AVI, hvorlangterder.dk, constructs measurements of distances from an address to conveniences and necessities such as hospitals, schools and shopping. Obtaining these distances for all of the listed housing and merging the two datasets, gives more opportunity for geographical-control. The data from hvorlangterder.dk will allow more micro-oriented differences within a given municipality. Which otherwise would not have been captured.

Måske en anden formulering ovenfor? Also scraping from statistik.politi.dk and Danmarks Statistik. By applying supervised machine learning on our combined dataset.

2 Data description

2.1 Data construction

Crime-rates. Traffic offences are not considered as a "serious" offence and are therefore neglected.

2.2 Exclusion of outliers

A few of the listed housing, have been for sale for over a decade. These are considered outliers, which are overly priced considering their characteristics. The outliers are excluded, because they would otherwise only contribute to a bias of overestimation. Number of excluded housing.

Danmark					
	Sjælland		Ikke Sjælland		
Type/Region	Hovedstaden	Sjælland	Syddanmark	Midtjylland	Nordjylland
Villa	513,36	459,67	503,62	461,96

3 Methods

3.1 Supervised Machine Learning

The objective by applying Machine Learning is to train a model that can predict pricing of housing listed in near future. Two types of predictive models will be used for the sake of returning different outputs: Regression-model to return the pricing as a continuous output. As well as a classification-model for predicting the interval which the price is included in.

3.2 Regularization / Lasso og derved variable selection

The use of a sizeable amount of regressors leads to a significant risk of over-fitting the prediction model. For the purpose of dealing with over-fitting, a form of regularization needs to be carried out. The Lasso-feature possesses the attributes to do so. Regularization by Lasso, will penalize complexity of the model by adjustment of parameter estimates. This penalty will make the model less complex and more appropriate for prediction.^{1 2}

The regularization parameter λ is determined by:

$$E_{\text{cv}} - \text{optimizeringsproblem}$$

Another convenient attribute of the Lasso-feature is that it produces regressions where some of the variables are set equal to zero³. Lasso thereby performs the variable selection.

6 Discussion

6.1 Data critique

Another interesting prediction which could have been obtained using the same methods, could have been to estimate expected selling prices. This could have been done simply by scraping data on sold housing instead. This could be of more value for private agents, whose main interest should be the selling price of their housing.

In a prediction-model like this it is near impossible to evade some form of omitted variable bias. A significant amount of potential important factors can not be acquired. For an example the view from the listed housing will for sure have great impact of the valuation price. Another factor of interest could have been a evaluation of the condition of the housing, unfortunately the "statement of property"red. (tilstandrapport) are not publicly accessible.
